PROGRAM FOR PREVENTION OF A CONSIDERABLE NUMBER OF PREMATURE BIRTHS

Erich Saling, Monika Dräger

REZUMAT

Obiective: Dezvoltarea unui program de prevenție a prematurității printr-un program incluzând măsuri de "Self Care" la gravide. Introducere: Prevenția prematurității înfântului de 32 săptămâni de sarcină și a prematurității cu feți sub 1500 de grame reprezintă una dintre cele mai importante probleme ale medicinei perinatale. În mod special considerăm că infecțiile genitale ascendente sunt cea mai frecventă cauză de năsture prematură. "Sistemul protectiv al lactobacililor" detine un rol deosebit în prevenirea acestor infecții. Vaginita bacteriană și/sau infecțiile genitale ascendente și au originea de regulă în o tulburare a mediuului vaginal – stare considerată a fi un "stadiu" precursor. Programul nostru de prevenție se bazează pe evaluarea riscului de năsture prematură pe baza anamnezei, a detectării semnelor precoce de alarmă (incluzând screeningul pentru semnele premergătoare infecției pe baza determinării pH-ului vaginal) și dacă este necesar implementarea măsurilor terapeutice necesare. Programul include pentru paciențele cu antecedente de nășteri prematură repetate măsuri de "Self Care" care ar trebui efectuate la toate gravidele, instituirea de măsuri terapeutice pentru paciențele la risc includând Ocluzia Totală Precoce a Cervixului (ETCO). Material și metode: Programul de măsuri "Self Care" este un program adițional îngrijirii prenatale. În studiul nostru au fost înrolate 1120 multiparae care s-au comparat rezultatul sarcinii actuale în care s-a implementat programul "Self Care" cu rezultatul sarcinii precedent. Ulterior programul a fost extins în lanul Thuringia (Germania). În două jumătăți ale anului 2000 programul "Self Care" a fost bugetat iar datele au fost comparate statistic cu cele din prima jumătate a anului 2000 perioadă ce nu a beneficiat de program (în fiecare jumătate de an sunt peste 8000 de nășteri). După acest studiu mai multe instituții de asigurare de sănătate au introdus programul "Self Care" în proiecte piloto pentru asigurările grădinar. Ocluzia Totală Cervicală Precoce (ETCO) este o măsură preventivă recomandată în special gravidele cu un anamneză cu unul sau mai multe avorturi mari (> 12 săptămâni gestaționale) sau năstări premature (< 32 săptămâni gestaționale) cu o etiologie infecțioasă a eventimentului sau a cazurilor la care altă cauză nu a fost detectată, dar a avut loc o ruptură spontană a membranelor. Ocluzia Precoce Totală a Cervixului (ETCO) realizează o barieră completă impotriva ascensiunii infecțiilor în canalul cervical (spre deosebire de cerclaj). Rezultate: A) Referitor la măsurile programului "Self Care": În toate studiile ratea nășterilor premature a fost redusă considerabil. Cele mai importante beneficii au fost obținute în special la nășteri cu risc foarte crescut. În colectivul nostru ratea de nășteri de copii foarte mici sub 1500 g a fost redusă de la 7,8% în sarcina precedentă la 1,3% în sarcina următoare în program. În Thuringia procentul de nou-născuți cu varsta sub 2300 g a fost redus de la 13,6% la 0,94%, respectiv a nou-născuților cu greutate sub 3500 g de la 6,1% la 0,38%. După ce campania din Thuringia a fost încheiată, rata de nășteri premature a crescut din nou. Prima evaluare a cazelor de asigurări din Landul German Nord Rhein Westfalia (NRW) a arătat că pacienții asigurați au o rata de nășteri premature de 7% comparativ cu 9,6% pentru întreaga populație a lanului NRW. În grupul nostru după efectuarea ETCO rata de nou-născuți au supraviețuit a fost de 80% comparativ cu 17% în sarcina precedentă în același grup. Rezultate similare la fel de bune au fost obținute și de alți clinicieni. Schulze (2008) a obținut la sarcina multipale de așa beneficiat de ETCO o rata de nășteri premature de doar 17% comparativ cu 29% în cazurile fără ETCO. Concluzii: Programul "Self Care" al gravidei a fost dovedit a fi o metodă foarte eficientă de prevenire a nășterii premature și ar trebui recomandat fiecărei gravide. În cazul în care nu este posibil, cel puțin medicii și moasele ar trebui să asigure pH-ul vaginal la fiecare consult prenatal. Ocluzia precoce totală a cervixului (ETCO) este o măsură eficientă de prevenire a nășterii premature la paciențele cu nășteri premature sau avorturi mari recurente. Programul "Self Care" a fost dovedit a fi o metodă foarte eficientă de prevenire a nășterii premature. Cu toate acestea, rata de nășteri prematură în grupul nostru este mai mică decât în grupul control. Cuvinte cheie: Prevenția prematurității, măsurarea pH-ului vaginal, infecții vaginale, self-care, ocluzia precoce totală a cervixului.

ABSTRACT

Objective: Prevention of prematurity by a prematurity-prevention-program, including "Self-Care"-measures for the pregnant women. Introduction: Prevention of early prematurity (< 32 gestational week = GW) and of very low birth weight infants (< 1500 g) is one of the most urgent tasks of perinatal medicine. Particularly ascending genital infection is the most important avoidable cause of early prematurity. For the prevention of these infections the protective lactobacillus system "plays a crucial role. Bacterial vaginosis and/or ascending genital infection start mostly with a disturbance of this vaginal environment – a stadiu considered as a "precursor". Our program is based on an anamnestic assessment of prematurity risk, the early detection of warning signs (including screening for pre-infection respective infection signs by regular measurement of the vaginal pH and, if necessary, the appropriate therapeutic measures. The program includes "Self-Care"-measures by the women themselves (preferably for all pregnant women) and additional special measures for women at risk, for example the Early Total Cervix Occlusion (ETCO) for women with recurrent premature births. Material and methods: The "Self-Care"-measures for pregnant women are an additional measure to regular prenatal care. In our own study we had 1120 multiparae and we compared the outcome of the pregnancy with self-care activities with the outcome of the immediate previous pregnancy. Our program was then used in the entire state of Thuringia (Germany). In the second half of the year 2000 the Self-Care-Program was employed and the statistically evaluated results for the entire state were compared with those from the first half of 2000 without the program (in each half-year there have been more than 8.000 births). After that, several German health insurance companies used our prenatal-care self-examination
program in a pilot project to their pregnant members. The Early Total Cervix Occlusion (ETCO) is a preventive measure particularly for cases with two or more late abortions (≥ 12+0 GW) or early premature births (<32+0 GW) in the patient’s history with either infection as cause for these events or when no other cause has been found, but when for instance premature rupture of membranes occurred. The Total Cervix Occlusion creates a complete barrier against ascending infections within the cervical canal (as opposed to the cerclage). **Results:** A) With regards to the “Self-Care”-measures: In all studies the rate of premature births could be considerably reduced. Most interesting are the results of the premature babies at particular high risk: In our collective the rate of very low birthweight infants (<1500 g) could be reduced from 7.8% in the immediate previous pregnancy to 1.3%. In Thuringia the rate of infants born <32+0 GW was reduced from 1.36 % to 0.94% respectively in infants < 1000g from 0.61% to 0.38%. After the campaign in Thuringia had been finished, the prematurity rates monitored in 2002 were again as high as before. The first evaluation of a health insurance company in the German state North-Rhine-Westfalia (NRW) shows that the insured patients had a prematurity rate of 7 % compared with the overall prematurity rate in NRW of 9.6 %. B) After an ETCO the rate of surviving infants was about 80% in our own population (as opposed to 17 % in the pregnancies before the ETCO in the same group). Similarly good results have been obtained by other clinicians. With ETCO in multiple pregnancies Schulze (2008) was able to achieve a prematurity rate of only 17% as against a rate of 29% in cases without ETCO. **Conclusion:** The Self-Care Program for pregnant women proved to be a very efficient method for the prevention of prematurity and should be recommended to every pregnant woman. In cases where this is not possible, at least doctors and midwives should measure the vaginal-pH at each prenatal care examination. The Early Total Cervix Occlusion is an effective preventive measure for women with recurrent late abortions or premature births and it seems to be also a good measure to prevent premature births in multiple pregnancies. More research in this area is necessary.  

**Key Words:** prematurity prevention, vaginal pH measurement, vaginal infection, Self-Care, Early Total Cervix Occlusion.

**INTRODUCTION**

Prematurity is still a major problem not only in the field of obstetrics and perinatal medicine but also for the society as a whole - not to mention the burdens for the concerned infants and their families. Particularly infants born before 32 weeks of gestation (GW) and/or with a birthweight lower than 1500g are at considerably higher risk of mortality and morbidity than infants born at term. Serious morbidity caused by prematurity include respiratory distress syndrome, intraventricular hemorrhage, periventricular leukomalacia and necrotising enterocolitis. Late sequelae include cerebral palsy, hearing and visual deficits, seizures and cognitive deficits.1,6

The situation is explosive. Despite of all the progress in perinatal medicine, the rate of premature births is increasing, also in developed countries. For example, in Germany, the rate of extremely premature born infants with less than 28 gw has increased from 0.37% in 2001 to 0.56% in 2006.7 This is an increase of 51%. In the USA there was a lower increase from 1.81% in 1981 to 2.0% in 2004 for the preterm with less than 32 gw.8

The reasons for the increase are probably the increased maternal age as well as the increase of the rate of multiple pregnancies as a result of assisted reproductive technologies.

Another problem, which is particularly relevant for the developing countries, is the increased susceptibility of preterm neonates to infections.

In addition, the financial burden of preterm birth is exceptionally high. For example, the Institute of Medicine of the National Academies of the United States has recently estimated that the cost of preterm birth is $26 billion per year in that country.9

**Causes of prematurity**

A number of reasons are known about late abortions and prematurity. Roberto Romero and his co-workers named it “Preterm Parturition Syndrome”.10 The causes are:

- Uterine overdistension;
- Ischaemia;
- Cervical disease;
- Abnormal allograft reaction;
- Allergic phenomena;
- Endocrine disorder;
- Infections (which are the main emphasis of our program).

As far as the avoidable causes are concerned, infections play the main role: ascending genital infection is known to be the main source – particularly of premature births below 32+0 gw. Back in 1991 we were able to find concrete signs of an infection in about three quarters of the infants with a birthweight of less than 2000g.11,12 The number of cases with premature rupture of membranes, was correspondingly high, namely 55%.

The association between bacterial vaginosis and prematurity is particularly remarkable. Maternal urinary tract infections or systemic infections can however also lead to premature birth (Screening for urinary tract infections is in many countries already part of routine care for pregnant women).

**The protective Lactobacillus System**

For the prevention of ascending vaginal infection the „protective lactobacillus system“ plays a crucial role. We can here only explain the essentials of it, but more details are to be found on: [http://www.saling-institut.de/eng/04infoph/01allg.html](http://www.saling-institut.de/eng/04infoph/01allg.html)13

The human vagina possesses a bio-system which...
under normal conditions provides a balance between physiologic lactobacilli and pathogenic bacterial flora, and so ensures a good protection against the spreading of pathogens, including their ascension to the uterine cavity.

In an article of particular interest to us, Gregor Reid described the role of lactobacilli in urogenital tract infections.14 The following main functions of lactobacilli are known:

1. They produce acids, mainly lactic acid;
2. They produce hydrogen peroxide ($H_2O_2$), which releases oxygen and has a disinfecting effect;
3. Bacteriocines inhibit the growth of pathogens which are always present in the vagina;
4. They produce biosurfactants, which cover the surface of the vaginal wall, thereby inhibiting the adhesion of pathogens;
5. They produce coaggregation molecules which block the spread of pathogens.

![Figure 1](http://www.saling-institut.de)

Figure 1. Protective vaginal bio-system: Functions of Lactobacilli (modified after Reid 2001) combined with our assessment that vaginal pH-measurement allows a diagnostic insight into this protective system like looking through a keyhole.

Not every lactobacillus strain produces all the factors mentioned above. That’s the reason why some strains are more effective against specific infections than others. For instance, women with $H_2O_2$-producing lactobacilli have a lower risk of suffering from Bacterial Vaginosis, than women whose lactobacilli don’t produce $H_2O_2$.15

Unfortunately there are also some microorganisms, whose growth is not or only marginally inhibited by lactobacilli (e.g. Streptococci and Candida). However, we can assume that lactobacilli are the main regulating factor of the vaginal milieu. Vaginal pH measurement gives us insight – like peering through a keyhole – into this protective bio-system. (Fig. 1) Vaginal pH measurement is therefore of essential value. It was already used 1892 by Döderlein in order to distinguish pathological from normal vaginal fluid.16

### Our Prematurity-Prevention-Program

After having been engaged in this field for more than 3 decades in 1989 we developed a new prematurity-prevention-program which is based mainly on the ascending infection concept. The original part with its 4 stages is intended for physicians. This overview, because of its comprehensive content, is less suited for a detailed presentation within such a contribution. Therefore we will limit our discussion to the essential part of this program. More details about this program and references are found on our homepage: [http://www.saling-institut.de](http://www.saling-institut.de).

The first stage is based on anamnestic load. A potentially increased risk is given in cases with anamnestic load such as one or more previous late spontaneous abortions or very premature labor. The best prophylactic countermeasure is to perform an operative Early Total Cervix-Occlusion (see below) at about 12 gw to create a barrier against the ascending of organisms.

The 2nd early stage of increased risk contains cases with a disturbance of the vaginal milieu – we consider it a “precursor” – which mostly can be detected by simple pH-measurement at the introitus. In such a case of so-called “dysbiosis”, a treatment with Lactobacillus acidophilus preparations on its own is recommended.

The 3rd stage of increased risk includes cases without symptoms of premature labor, but in which proven vaginal infection is present such as bacterial vaginosis, Chlamydia infection of the cervical canal or urethra or significant bacteriuria. In such cases, antiseptic, respectively local chemotherapeutic measures and local or systemic antibiotic therapy are recommended. The chances of success are still favorable.

The 4th and most progressed stage involves cases with symptoms of prematurity such as apparent premature uterine contractions and/or critical ultrasonic findings of the cervix. In this last stage, the therapeutic measures are increasingly unsuccessful.

Another important risk of prematurity which belongs to our medical part of the prevention program is the occurrence of significant bacteriuria which has been known as a cause of prematurity for a long time. Also, in the last decade, evidence was found for correlations between periodontitis and premature births.17

### Screening for pre-infection, respective infection signs

The main emphasis of our program lies however in screening each pregnant woman for pre-infection signs, or if this has been started too late, for infection signs. We assume that the unexpected high successes in the reduction of prematurity rates - achieved by our self-care-measures - are based on the following new
opportunity: never before was it possible to detect the first disturbances of vaginal milieu in such an early stage and to start with therapeutic countermeasures so early (s. also under Self-Care-Program).

In cases where prematurity is caused due to other reasons, the possibility of intervention and successful therapy are clearly not so good. The measurement of the vaginal pH-value is particularly important. We have been recommending this measure already since 1989 for the regular prenatal care.\(^1\)\(^8\)\(^9\) Currently we are performing an enquiry with regard to regular prenatal care in Germany at the present time. According to our first evaluation, about 2/3 of the physicians, who returned the forms, do measure the vaginal pH of their patients regularly. An increase in the pH-value (≥ 4.2 if measured with pH-meter, > 4.4 if measured with indicator paper)\(^1\) can refer to:

- Disturbance in the vaginal milieu, the so-called “dysbiosis”;
- Bacterial vaginosis - diagnostic clinical criteria in addition to an increased vaginal pH (≥ 4.5) are suggestive.\(^20\)
- Aerobic vaginitis;\(^21\)
- More rarely another infection. If other infections are suspected, an appropriate examination should be carried out.

The treatment will be performed according to the situation. Here are just the most common indications:

1. **Disturbances of the vaginal milieu** without signs of bacterial vaginosis or other specific infection: after our experiences lactobacillus preparations provide the best treatment in these cases.

2. If bacterial vaginosis is diagnosed it should be treated either locally or systemically with Metronidazole or Clindamycin.

3. Other specific infections should be treated accordingly.

\(^1\) Devices for the measurement of the vaginal pH: A simple and, if used for the examination of many patients, inexpensive way of measuring the pH is to use a small, portable pH-meter. Another alternative, a little more expensive, is the use of indicator strips which are introduced into the area of the introitus vaginae with the finger either before or after the vaginal examination and compared with the corresponding color scale. We made by far the best experiences, when using “Spezialindikator pH 4.0-7.0”; art-no. 1.09542 by Merck, Darmstadt (Germany), because reading is here especially easy and reliable. In the meantime, special disposable gloves with the indicator paper from Merck fixed on the index finger are available for use by the physician. The gloves are almost identical to the ones that we recommend for the patients (see below).

The only difference is, that the paper in the version for the physician is attached to the middle phalanx of the index finger, so that during vaginal examination the pH value will be measured automatically at the lower part of the vagina.

**Self-Care-Program for pregnant women**

The “Self-Care”-measures for pregnant women form the most important part of our Prematurity-Prevention-Program.\(^22\)\(^23\) We recommend that each pregnant patient measures her vaginal pH from the beginning of the pregnancy using a CarePlan\(^R\) V pH-test-glove which we developed in collaboration with a Medical Company. The indicator can be compared with a color chart and the pH-value read. If the pH is normal, this means 4.4 or less the indicator turns yellow. (Fig. 2)
Changes in vaginal discharge,
- Burning and itching in the intimate regions,
- Signs of urinary tract infection,
- Menstruation-like pains etc.
- Vaginal bleeding or spotting.

For more details, please see: [http://www.saling-institut.de/eng/04infoph/03selbst.html](http://www.saling-institut.de/eng/04infoph/03selbst.html).

### RESULTS

Our results have repeatedly been published.11,12,22-26

Just a few results concerning the Self-Care-Program should be mentioned:

- The rate of low birthweight infants (< 2500g) in those patients taking part in the Self-Care-Program and who had been pregnant before was 6.2%, this means three times less than in immediate previous pregnancies, when it had been 18.3%.
- It is of special interest to note that the number of very underweight infants (< 1500g) was 1.3 % that is six times lower than in the immediate previous pregnancies, when it had been 7.8%.
- The rate of extremely underweight infants (< 1000g) amounted to 0.9%, as opposed to 3.9% previously.

### Results from other places

Later Hoyme and al. achieved similar encouraging results with our program in a prospective project undertaken in Erfurt, the capital of Thuringia, Germany.27

The excellent results encouraged the Government of Thuringia to employ our program on approval in their whole state. In the second half of the year 2000 the Self-Care-Program was employed and the statistically evaluated results for the entire state were compared with those from the first half of 2000 without the program (in each half-year there have been more than 8,000 births).

The results are impressive and - from our point of view - represent a breakthrough, in so far as most authors dealing with prematurity stated that in greater population areas the prematurity rate has not changed at all during the previous decades.

In Thuringia the results were: 27,29
- With regard to gestational weeks: the rate of very early born infants with less than 32 gw was 1.36% in the first half of the year 2000, and 0.94% in the second half. This is a significant reduction.
- With regard to birthweight: in infants below 1500g birthweight the rate decreased from 1.29% to 0.97%. In infants with less than 1000g the decrease was significant from 0.61% to 0.38%. This is an even greater decrease.
- Also cases with premature rupture of membranes (PROM) have been significantly reduced. While in the first half of the year 2000 the frequency of PROM in cases where the infants have been born with less than 32 gw was 0.55% out of 7,870 deliveries it has been significantly reduced in the 2nd half of the year to 0.2% out of 8,406 deliveries.
- In the meantime a statistical cross check is available.28,29

After this campaign had been finished, the prematurity rates monitored in 2002 were again as high as they had been prior to the introduction of the activities. Figure 3 shows the numbers for children with a birthweight < 1000 g. We see in these results a confirmation for the efficiency of the program and it compensates to a certain degree the fact that randomised controlled studies are still not available (see also the discussion below). (Fig. 3)

![Birth weight < 1000g State of Thuringia](attachment:image.png)

**Figure 3.** Statistical crosscheck between the results from the campaign (red column) with previous and later years (after Hoyme et al 2005 b)

Encouraged by these excellent results several German health insurance companies conducted our prenatal-care self-examination program as a pilot project to their pregnant members at no charge. The companies started this project in December 2003, the official results are not available yet, but after first internal evaluations, they have already saved a high amount of expenses.

A separate study is currently being conducted by a group of other health insurance companies in the German state North-Rhine-Westfalia with the participation of 780 gynecologists. The first results of their evaluation of the so-called “Hallo-Baby” project shows that the insured patients had a prematurity rate of 7% compared with the overall prematurity rate in NRW of 9.6%.30
Pregnancies with anamnestic risk

Recurrent late abortions or preterm births

After one preterm birth in the history, the risk of a recurrent preterm birth is increased, the actual recurrence risk depending on the cause and also on the gw when the preterm birth or late abortion occurred: the earlier in pregnancy, the higher the risk for recurrence. McManemy et al. found also, that in cases with two previous pregnancies, the risk is higher (21%) if the sequence of previous pregnancies was term/preterm and lower (13%) if the sequence was preterm/term. After 2 preterm deliveries the risk for recurrence is about 40% - depending on the gw: 33% for 2 prior preterm deliveries between 32-36 gw and 57% in cases with 2 prior deliveries between 21-31 gw.

Particularly in cases with two or more late abortions (≥ 12+0 gw) or early premature births (<32+0 gw) in the patient’s history with either infection as cause for these events or when no other cause has been found, but when for instance premature rupture of membranes occurred, we recommend an Early Total Cervix Occlusion (ETCO) as preventive measure. (Fig.4) Please note, that the main reason for premature rupture of the membranes is ascending vaginal infection. The Total Cervix Occlusion (TCO) creates a complete barrier against ascending infections within the cervical canal (as opposed to the cerclage, see below). We introduced this measure in 1981.

The rate of surviving children after an ETCO was about 80% in our own population (as opposed to 17% in the pregnancies before the ETCO in the same group). Similarly good results have been obtained by other clinicians performing the Total Cervix Occlusion (TCO): In 1996 we reported the results of a multi-center-evaluation, in which 11 German hospitals took part and the outcome of a total of 819 pregnancies with TCO was assessed. It emerged that the rate of surviving infants in the pregnancies before TCO had been performed was 21% compared to 74% in the pregnancies with TCO. Hormel and Künzel reported similar good results.

This operation is now an essential part of our Prematurity-Prevention-Program and also a widespread measure in German speaking countries. Our “Early Total Cervix-Occlusion” is in principle quite different from a pessary or the cerclage. (Fig. 4) The latter only allows to tighten the cervical canal. Now as before microorganisms can ascend into the uterus. Therefore the success rate to achieve a surviving infant in pregnancies with cerclage has been only 26% compared with 80% after ETCO. However, our operative occlusion, creates a complete barrier within the cervix to prevent ascension of organisms.

Other measures concerning recurrent preterm birth, e.g. measurement of cervical length, fetal fibronectin or progesterone application are in the literature partially controversially discussed.

Multiple pregnancies

Another group with higher risk are multiple pregnancies. The fact is important that our Self-Care-Program enables us to remarkably reduce the number of premature births also in multiple pregnancies. In Thuringia the frequency of twins and triplets with birthweight lower than 1,500 g has been reduced from about 27% without the Self-Care-Program to about 14% with the program and in the group of extreme low birthweight of less than 1000 g from 11.6% to 2.0%.

But there is also another new additional chance to achieve success in multiple pregnancies. The basis is an interesting measure from G. Schulze. Already in 1990 Schulze started to perform our operative ETCO not only in cases with recurrent miscarriages but also in multiple pregnancies in general. With ETCO in multiple pregnancies in about 100 cases he was able to achieve a prematurity rate of only 17% as against a rate of 29% in cases without ETCO. So in cases with ETCO there has been a reduction of about 40%. We are convinced that this is an additional efficient method to reduce the frequency of prematures in multiple pregnancies. Further research needs to be done to evaluate in which cases with multiple pregnancies screening for pre-infections and infections by the physician respectively midwife plus additional pH-self measurement by the
pregnant women themselves is sufficient and which patients might benefit from an additional ETCO.

DISCUSSION AND CONCLUSION

Internationally, a lot of research is done in the field of prematurity prevention. Particularly in the field of infections, there are some promising approaches, such as „graded measures“, e.g. measurement of the cervical length and – if the cervix is shortening – measurement of fetal fibronectine and then according to that result further measures.42 However, from our point of view, most of these measures start at an already advanced stage of the prematurity process.

Also, we should not rely too much on the opinion that most things in medicine are or must be very complicated. No, besides from such complexes like for instance in our field “Great Obstetrical Syndroms” there are also surprisingly simple solutions to prevent risks of health.10 As we for instance know from history of puerperal sepsis, Ignaz Semmelweis has shown that an elementary measure like washing the hands with disinfectants can prevent infection and can save many of human lives. Naturally we can be proud of the current fascinating – often highly sophisticated - progress in human medicine, particularly in last decades in our pre- and perinatal medicine. But we should not ignore or forget that there are – now as before – also simple ways to achieve safety for our patients.

Currently the Self‑Care‑Program – as has been confirmed by our evaluation and afterwards by two prospective investigations by Hoyne and al (see above) – seems to be the most efficient, easily applicable and inexpensive program for prevention of very early prematurity. The explanation of the so positive results which we achieved, may be due to the fact that our prevention program, which appears to be elementarily simple – with the help of the cooperating pregnant patient – allows to detect the very first disturbances of the vaginal ecosystem long enough before any concrete symptoms of infection – including bacterial vaginosis and aerobic vaginitis – are evident. This enables immediate therapeutic measures, leading to a rapid reestablishment of normal vaginal milieu and probably prevents some of the later stages of the so complicated prematurity complex or how it was named by Prof. Roberto Romero as one of the ”Great Obstetrical Syndromes”.

Thus the Self‑Care‑Program for pregnant women has a high importance in the field of health and social care and has considerable value within our social community. We therefore recommend this measure for all pregnant women as a basic procedure. In countries, where the circumstances do not allow to employ the self-care measures for all women, at least pH-measurement by physicians or midwives should be performed regularly. Additionally other, more sophisticated measures may be necessary in special cases. For women with recurrent preterm births with either infection as cause for these events or when no other cause has been found, from our point of view the ETCO is the best solution.

Randomized studies and evidence based medicine

We are aware, that in times of evidence-based medicine prospective randomized trials are – or at least seem to be – “standard of art” to prove the effectiveness of a given measure. But we should not rely too much on the current and so dominating opinion that “randomized controlled studies” and the so-called “evidence based medicine” are the only reliable ways to differentiate between efficient and inefficient medical measures. Such simple maneuvers like washing the hands has never been proved by randomized controlled studies (Semmelweis performed rather an “observational study”) but nevertheless his measure was highly efficient and a real breakthrough.

We should not renounce on simple practical thinking and should at the same time use our common sense. Also old traditional methods had their validity of finding out efficient diagnostic and therapeutic processes. We are not alone with such opinions. So for instance Peter Dunn a well-known British neonatologist published the following statement: “Nor do I need to remind you that Medicine is an Art as well as a Science and that every patient – allow me to include every midwife and every physician – is a unique individual who does not necessarily conform to the conclusion of a metaanalyzer. We must be careful not to rely on high technology to the extent that we allow our clinical skills and judgment to atrophy.”46

Therefore, although it would be possibly more convincing for the international community, if we had randomized trials for both the Self‑Care‑Program and the ETCO, we don't think that it is necessary to prove its efficiency. Also, after the above discussed good results and also after the study performed by several health insurances companies, it seems to be impossible to perform a randomized trial in Germany. It is most unlikely that after all these results a protocol for a randomized study with some women measuring their pH-value and some not (or without therapeutic consequences) would pass any ethical council in Germany - and in any case, our own ethical conscience would not allow to design such a study.
The same argument is valid for the ETCO. It is by now a widespread measure in Germany with excellent results.2

The situation may be different in countries where either the measurement of the vaginal pH by the physician and/or the self measurement by the women themselves is not yet performed that widely. The same is true for the ETCO. Therefore, if individual scientists or study groups consider a randomized trial with either the pH-measurement or the ETCO, we would welcome it very much and would support them with any advice or assistance, if necessary.

Currently, we are preparing an “International Prematurity Prevention Project (IPPP)” aiming for international cooperation with national societies of perinatal medicine, societies of obstetrics and maternal fetal medicine, institutions of medical and social affairs within the national governments as well as individual scientists and study groups. This program is intended to incorporate easily applicable measures for the prevention of prematurity into the prenatal care of participating countries. We plan to invite these societies and individuals to take part in this project by evaluating and implementing either the program as a whole or only “modules” such as the vaginal pH-measurement. Information about the IPPP will soon be available on: www.prematurity-prevention.org

ACKNOWLEDGEMENT

On www.saling-institut.de you can find detailed information about the Prematurity-Prevention-Program, the Self-Care-Program and the Early Total Cervix Occlusion (ETCO). On the Website there is also a self-made video to be downloaded on how to perform the ETCO.
